The muskoxen, on the other hand, have evolved in just the opposite direction, becoming bigger and more bulky as the climate has warmed, the researchers found. These changes, known as "ecological speciation," could cause a big upheaval for wildlife conservation efforts, said Meredith S. Nisbet, a graduate student at the University of Chicago who led the study. "We have to think about the Arctic differently," she said. The research, published Thursday in the journal Science, offers the first broad picture of how the far north's various ecological groups have changed since the end of the last ice age, roughly 14,500 years ago. The study comes on the heels of the Paris Climate Agreement, which calls on nations to preserve and protect the Arctic's tundra, seascapes and wildlife — including a set of marine mammals known as the ice seals. Wildlife in the Arctic, which used to be found on the ground and in lakes, have since retreated to the far north, where the climate is cold and challenging, with cold temperatures lasting well into the summer.
